

**LIST OF CURRENT CLAIMS**

1. (Previously Presented) Method for adjusting a compressed air installation with several compressors, said installation comprising two or more electrically driven compressors of the kind known as any of the designations: 'loaded/unloaded' compressor; turbo compressor; and variable rotational speed compressor, said compressors being connected to a single compressed air network via their respective outlet, and wherein each compressor is provided with at least one control unit, and further wherein a control box to which is connected a pressure sensor comprising part of said compressed air network is used, said control box enabling adjustment of the pressure in said compressed air network relative to a settable target pressure and within a pressure range which is limited by a minimum pressure to be set and a maximum pressure to be set, and wherein the adjustment takes place by controlling the flow of one or several of the compressors in order to increase the overall flow supplied by the compressors when the pressure drops below a desired level, and in order to lower the overall supplied flow when the pressure exceeds a desired level.

2. (Previously Presented) Method according to claim 1, wherein the control box controls the overall flow of the compressed air installation by giving at least one control order to the control unit of a compressor, which control orders may include one or more orders selected from the group consisting of starting and/or stopping one or several compressors; opening or closing a controlled inlet valve of one or several compressors; opening or closing an exhaust valve of one or several compressors to a more or lesser degree; and adjusting the rotational speed of one or several compressors.

3. (Previously Presented) Method according to claim 1, wherein, when the pressure in the compressed air network rises above the set target pressure, the control box will increase the overall flow a certain length of time before the set maximum pressure is reached, and when the pressure in the compressed air network drops below the set target pressure, the control box will reduce the overall flow a certain length of time before the set minimum pressure is reached.

4. (Previously Presented) Method according to claim 1, wherein an evaluation table is stored in the memory of the control box beforehand for every compressor or for every type of compressor of the compressed air installation, such that for every working condition of the respective compressor, the influence of a control order is assessed, and such that for every control order of the compressor concerned, a score is given which is positive when the influence of said order is favourable to the output of the compressed air installation, and which is negative when the influence is unfavourable, and whose absolute value increases as the favourable or unfavourable influence increases.

5. (Previously Presented) Method according to claim 4, wherein, while the compressed air installation is operational, in order to select the most favourable control order of the scores, the scores of all positive control orders which can direct the overall flow in the required direction in order to bring the pressure in the compressed air network closer to the set target pressure, can be mutually compared by an algorithm, either periodically or continuously, after which the control order concerned with the highest score is implemented.

6. (Previously Presented) Method according to claim 5, wherein the algorithm, when selecting the most favourable control order, also takes into account the overall score of combined control orders of one or several compressors which can direct the overall flow in the required direction, such that the control order or combined control order having the highest score is subsequently carried out.

7. (Previously Presented) Method according to claim 5, wherein in order to select the most favourable control order, the scores of the control orders are increased by a value which is equal to the difference between the supplied flow and the required flow after a hypothetical implementation of the control order concerned, multiplied by a negative weighing factor whose absolute value is bigger in the case where said difference is positive than in the case where said difference is negative.

8. (Previously Presented) Method according to claim 5, wherein in order to select the most favourable control order, the scores of the control orders are increased by a value which is equal to the difference between the supplied flow before the control order and the hypothetically supplied flow following the control order, multiplied by a negative weighing factor.

9. (Previously Presented) Method according to claim 5, wherein if an even wear is required for all the compressors, a value is added to the scores which is equal to the number of working hours of each respective compressor, multiplied by a negative weighing factor.

10. (Previously Presented) Method according to claim 5, wherein if a forced priority for starting the compressors is required, a starting priority is accorded to the compressors which is added to the above-mentioned scores after multiplication with a negative weighing factor.

11. (Previously Presented) Method according to claim 5, wherein if a low selection priority is required for a compressor, a positive value will be added to the scores of the respective compressor which is all the greater as the priority is low.

12. (Currently Amended) Control box for adjusting a compressed air installation comprising at least one compressor ~~or several compressors~~ according to the method of claim 1, said control box comprising: having connections to at least one ~~or several~~ control unit ~~units of said at least one compressor~~ ~~the compressors for the connection of the control box and with~~ and to a pressure sensor of comprising the compressed air installation; a memory arranged to store ~~in which can be stored~~ an evaluation table with scores to be inputted by a ~~the~~ user; ~~[[/]]~~ and an arithmetic unit with an algorithm which enables comparison between said ~~makes it possible to compare the aforesaid~~ scores and to provide ~~give~~ a control order as a function of a ~~the~~ highest selected score.

13. (Previously Presented) Compressed air installation for carrying out the method according to claim 1, comprising one or more compressors selected from the group of compressor types consisting of 'loaded/unloaded' compressor; turbo compressor; and variable rotational speed compressor, wherein the compressors are each connected to a single compressed air network via their outlets, and wherein each compressor is provided with one or several control units; a pressure sensor; and a control box which is connected to one or several of the control units and to the pressure sensor.
